Support Vector Machines

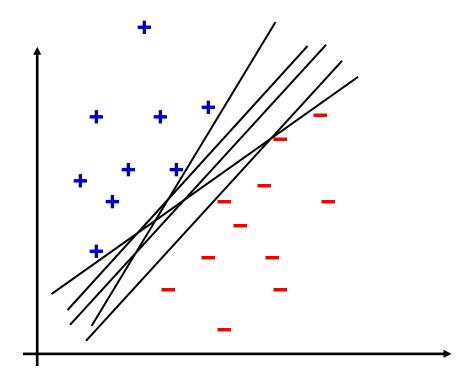

Perceptron Revisited: Linear Separators

 Binary classification can be viewed as the task of separating classes in feature space:

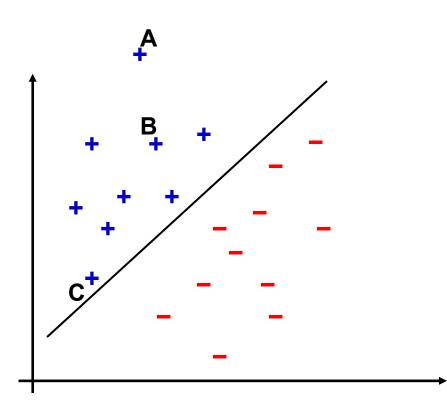

Linear Separators

Which of the linear separators is optimal?

Intuition of Margin

- Consider points A, B, and C
- We are quite confident in our prediction for A because it is far from the decision boundary.
- In contrast, we are not so confident in our prediction for C because a slight change in the decision boundary may flip the decision.

Given a training set, we would like to make all predictions correct and confident! This leads to the concept of margin.

Functional Margin

 Given a linear classifier parameterized by (w, b), we define its functional margin w.r.t training example (xⁱ, yⁱ) is defined as:

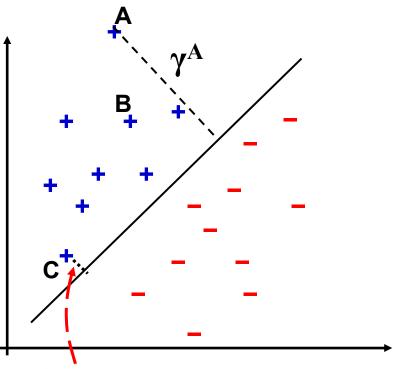

$$\widehat{\gamma}^i = y^i(\mathbf{w} \cdot \mathbf{x}^i + b)$$
 Note that $\widehat{\gamma}^i > 0$ if classified correctly

- If we rescale (**w**, b) by a factor α , functional margin gets multiplied by α
 - we can make it arbitrarily large without change anything meaningful
 - Instead, we will look at geometric margin

Geometric Margin

- The geometric margin of (w, b)
 w.r.t. x⁽ⁱ⁾ is the distance from x⁽ⁱ⁾ to the decision surface
- This distance can be computed as

$$\gamma^{i} = \frac{y^{i}(\mathbf{w} \cdot \mathbf{x}^{i} + b)}{\|\mathbf{w}\|}$$

Given training set S={(xⁱ, yⁱ): i=1,..., N}, the geometric margin of the classifier w.r.t. S is

$$\gamma = \min_{i=1\cdots N} \gamma^{(i)}$$

Points closest to the boundary are called Support vectors – we will see that these are the points that really matters

Maximum Margin Classifier

- Given a linearly separable training set S={(x(i), y(i)): i=1,..., N}, we would like to find a linear classifier with maximum margin.
- This can be represented as an optimization problem.

$$\max_{\mathbf{w},b,\gamma} \gamma$$
subject to: $y^{(i)} \frac{(\mathbf{w} \cdot \mathbf{x}^{(i)} + b)}{\|\mathbf{w}\|} \ge \gamma, \quad i = 1,\dots, N$

Nasty optimization problem! Let's make it look nicer!

• Let $\gamma' = \gamma \cdot ||\mathbf{w}||$, this is equivalent to

$$\max_{\mathbf{w},b,\gamma'} \frac{\gamma'}{\|\mathbf{w}\|}$$

subject to: $y^{i}(\mathbf{w} \cdot \mathbf{x}^{i} + b) \ge \gamma', i = 1,\dots, N$

Maximum Margin Classifier

• Note that rescaling **w** and *b* by $(1/\gamma^2)$ will not change the classifier, we can thus further reformulate the optimization problem

$$\max_{\mathbf{w},b} \frac{\gamma'}{\|\mathbf{w}\|}$$
subject to: $y^{i}(\mathbf{w} \cdot \mathbf{x}^{i} + b) \ge \gamma', i = 1,\dots, N$

$$\max_{\mathbf{w},b} \frac{1}{\|\mathbf{w}\|} \text{ (or equivalently } \min_{\mathbf{w},b} \|\mathbf{w}\|^{2})$$
subject to: $y^{i}(\mathbf{w} \cdot \mathbf{x}^{i} + b) \ge 1, i = 1,\dots, N$

Maximizing the geometric margin is equivalent to minimizing the magnitude of **w** subject to maintaining a functional margin of at least 1

Solving the Optimization Problem

$$\min_{\mathbf{w},b} \frac{1}{2} \|\mathbf{w}\|^2$$

subject to: $y^i(\mathbf{w} \cdot \mathbf{x}^i + b) \ge 1, \quad i = 1, \dots, N$

- This results in a quadratic optimization problem with linear inequality constraints.
- This is a well-known class of mathematical programming problems for which several (non-trivial) algorithms exist.
 - One could solve for w using any of these methods
- We will see that it is useful to first formulate an equivalent dual optimization problem and solve it instead
 - This requires a bit of machinery

Aside: Constrained Optimization

To solve the following optimization problem

$$\min_{\mathbf{x}} f(\mathbf{x})$$
 subject to $g_i(\mathbf{x}) \leq 0$ for $i = 1, \dots, m$

Consider the following function known as the Lagrangian

$$\mathcal{L}(x,\alpha) = f(\mathbf{x}) + \sum_{i} \alpha_{i} g_{i}(\mathbf{x})$$

Under certain conditions it can be shown that for a solution x' to the above problem we have

$$f(x') = \min_{x} \max_{\alpha} \mathcal{L}(x,\alpha) = \max_{\alpha} \min_{x} \mathcal{L}(x,\alpha)$$
 Primal form Dual form subject to $\alpha_i \geq 0$

Back to the Original Problem

Minimize
$$\frac{1}{2}||\mathbf{w}||^2$$

subject to:
$$1 - y^i(\mathbf{w} \cdot \mathbf{x}^i + b) \le 0$$
, $i = 1, \dots, N$

The Lagrangian is

$$L(\mathbf{w}, b, \boldsymbol{\alpha}) = \frac{1}{2} \mathbf{w} \cdot \mathbf{w} + \sum_{i=1}^{N} \alpha_i \{1 - y^i (\mathbf{w} \cdot \mathbf{x}^i + b)\}, \text{ subject to } \alpha_i \ge 0$$

• We want to solve $\max_{\alpha} \min_{w,b} \mathcal{L}(w,b,\alpha) \ s.t. \ \alpha_i \geq 0$

Setting the gradient of \mathcal{L} w.r.t. w and b to zero, we have

$$\mathbf{w} - \sum_{i=1}^{N} \alpha_i y^i \mathbf{x}^i = 0 \quad \Longrightarrow \quad \mathbf{w} = \sum_{i=1}^{N} \alpha_i y^i \mathbf{x}^i$$

$$\sum_{i=1}^{N} \alpha_i y^i = 0$$

The Dual Problem

If we substitute $\mathbf{w} = \sum_{i=1}^{n} \alpha_i y^i \mathbf{x}^i$ to \mathcal{L} , we have

$$\begin{split} L(\boldsymbol{\alpha}) &= \frac{1}{2} \mathbf{w} \cdot \mathbf{w} - \sum_{i=1}^{N} \alpha_{i} \{ y^{i} (\mathbf{w} \cdot \mathbf{x}^{i} + b) - 1 \} \\ &= \frac{1}{2} \sum_{i=1}^{N} \sum_{j=1}^{N} \alpha_{i} \alpha_{j} y^{i} y^{j} < \mathbf{x}^{i} \cdot \mathbf{x}^{j} > - \sum_{i=1}^{N} \sum_{j=1}^{N} \alpha_{i} \alpha_{j} y^{i} y^{j} < \mathbf{x}^{i} \cdot \mathbf{x}^{j} > - b \sum_{i=1}^{N} \alpha_{i} y^{i} + \sum_{i=1}^{N} \alpha_{i} \alpha_{i} y^{i} + \sum_{i=1$$

- Note that $\sum_{i=1}^{N} \alpha_i y^i = 0$
- This is a function of α_i only

The Dual Problem

- The new objective function is in terms of α_i only
- It is known as the dual problem: if we know all α_i , we know \mathbf{w}
- The original problem is known as the primal problem
- The objective function of the dual problem needs to be maximized!
- The dual problem is therefore:

$$\max L(\boldsymbol{\alpha}) = \sum_{i=1}^{N} \alpha_i - \frac{1}{2} \sum_{i=1}^{N} \sum_{j=1}^{N} \alpha_i \alpha_j y^i y^j < \mathbf{x}^i \cdot \mathbf{x}^j >$$

subject to $\alpha_i \ge 0, i = 1,...,n$,

Properties of α_i when we introduce the Lagrange multipliers

$$\sum_{i=1}^{N} \alpha_i y^i = 0$$

The result when we differentiate the original Lagrangian w.r.t. b

The Dual Problem

$$\max L(\boldsymbol{\alpha}) = \sum_{i=1}^{N} \alpha_i - \frac{1}{2} \sum_{i=1}^{N} \sum_{j=1}^{N} \alpha_i \alpha_j y^i y^j < \mathbf{x}^i \cdot \mathbf{x}^j >$$
subject to $\alpha_i \ge 0, i = 1, ..., n,$
$$\sum_{i=1}^{N} \alpha_i y^i = 0$$

- This is also quadratic programming (QP) problem
 - ullet A global maximum of α_i can always be found
- w can be recovered by $\mathbf{w} = \sum_{i=1}^{N} \alpha_i y^i \mathbf{x}^i$
- b can also be recovered as well (wait for a bit)

Characteristics of the Solution

- Many of the α_i are zero
 - w is a linear combination of only a small number of data points
- In fact, optimization theory requires that the solution to satisfy the following KKT conditions:

$$\alpha_i \ge 0, i = 1, ..., n,$$

$$y^i \left(\sum_{j=1}^N \alpha_i y^j < \mathbf{x}^j \cdot \mathbf{x}^i > + b \right) \ge 1$$
Functional margin ≥ 1

$$\alpha_i \{ y^i (\sum_{j=1}^N \alpha_i y^j < \mathbf{x}^j \cdot \mathbf{x}^i > + \mathbf{b}) - 1 \} = 0 \qquad \text{a}_i \text{ is nonzero only when functional margin } = 1$$

- \mathbf{x}_{i} with non-zero α_{i} are called support vectors (SV)
 - The decision boundary is determined only by the SV
 - Let t_i (j=1, ..., s) be the indices of the s support vectors. We can write $\mathbf{w} = \sum_{i=1}^{n} \alpha_{t_j} y^{t_j} \mathbf{x}^{t_j}$

Solve for b

- Note that we know that for support vectors the functional margin = 1
- We can use this information to solve for b
- We can use any support vector to achieve this

$$y^{i}(\sum_{j=1}^{s} \alpha_{t_{j}} y^{t_{j}} < \mathbf{x}^{t_{j}} \cdot \mathbf{x}^{i} > + b) = 1$$

 A numerically more stable solution is to use all support vectors (details in the book)

Classifying new examples

- For classifying with a new input z
 - Compute $\mathbf{w}^T\mathbf{x} + b = \sum_{j=1}^{\infty} \alpha_{t_j} y^{t_j} < \mathbf{x}^{t_j} \cdot \mathbf{x} > +b$ and classify \mathbf{z} as positive if the sum is positive, and negative otherwise
 - Note: w need not be formed explicitly, rather we can classify z by taking a weighted sum of the inner products with the support vectors
 (useful when we generalize from inner product to kernel functions later)

The Quadratic Programming Problem

- Many approaches have been proposed
 - Loqo, cplex, etc. (see http://www.numerical.rl.ac.uk/qp/qp.html)
- Most are "interior-point" methods
 - Start with an initial solution that can violate the constraints
 - Improve this solution by optimizing the objective function and/or reducing the amount of constraint violation
- For SVM, sequential minimal optimization (SMO) seems to be the most popular
 - A QP with two variables is trivial to solve
 - Each iteration of SMO picks a pair of (α_i, α_j) and solve the QP with these two variables; repeat until convergence
- In practice, we can just regard the QP solver as a "black-box" without bothering how it works

A Geometrical Interpretation
